Semester : 4th

Engineering Ethics

Assignment Submission

In the presented case study , Rachel as an Quality Assurance Engineer, is in dilemma with the decision to release a product or not. She strictly adheres to a policy, refraining from shipping any product that may potentially malfunction causing physical harm to the customer. However, she is willing to release a product with a minor likelihood of failure resulting in data loss as failure to do so might allow her company's competitor to gain a competitive edge.

The first option of solution, which involves not releasing any product until data loss issue is resolved, might lead to financial setbacks, company falling behind its competitors even Rachel causing her job. On the other hand, the second option raises concerns about potential data loss, which could discourage present and future customers from choosing the company's products.

Given this dilemma, I believe the most ethical solution for Rachel is not to release the faulty product. However, Rachel could work with her team to explore ways to expedite testing processes without compromising quality or investigate options for minimizing the data loss as much as possible while meeting the deadlines and then release the product with as less fault as possible. Despite the potential short-term competitive disadvantages, it ensures the preservation of the company's brand integrity, long-term loyalty and satisfied customers.
